

DFA Minimization

DFA Minimization using Myhill-Nerode Theorem

Algorithm

Input – DFA

Output – Minimized DFA

Step 1 – Draw a table for all pairs of states (Q_i, Q_j) not necessarily connected directly [All are unmarked initially]

Step 2 – Consider every state pair (Q_i, Q_j) in the DFA where $Q_i \in F$ and $Q_j \notin F$ or vice versa and mark them. [Here F is the set of final states]

Step 3 – Repeat this step until we cannot mark anymore states –

If there is an unmarked pair (Q_i, Q_j) , mark it if the pair $\{\delta(Q_i, A), \delta(Q_j, A)\}$ is marked for some input alphabet.

Step 4 – Combine all the unmarked pair (Q_i, Q_j) and make them a single state in the reduced DFA.

Example

Let us use Algorithm 2 to minimize the DFA shown below.

Step 1 – We draw a table for all pair of states.

	a	b	c	d	e	f
a						
b						
c						
d						
e						
f						

Step 2 – We mark the state pairs.

	a	b	c	d	e	f
a						
b						
c	✓	✓				
d	✓	✓				
e	✓	✓				
f			✓	✓	✓	

Step 3 – We will try to mark the state pairs, with green colored check mark, transitively. If we input 1 to state 'a' and 'f', it will go to state 'c' and 'f' respectively. (c, f) is already marked, hence we will mark pair (a, f). Now, we input 1 to state 'b' and 'f'; it will go to state 'd' and 'f' respectively. (d, f) is already marked, hence we will mark pair (b, f).

	a	b	c	d	e	f
a						
b						
c	✓	✓				
d	✓	✓				
e	✓	✓				
f	✓	✓	✓	✓	✓	

After step 3, we have got state combinations {a, b} {c, d} {c, e} {d, e} that are unmarked.

We can recombine {c, d} {c, e} {d, e} into {c, d, e}

Hence we got two combined states as – {a, b} and {c, d, e}

So the final minimized DFA will contain three states {f}, {a, b} and {c, d, e}

DFA Minimization using Equivalence Theorem

If X and Y are two states in a DFA, we can combine these two states into $\{X, Y\}$ if they are not distinguishable. Two states are distinguishable, if there is at least one string S , such that one of $\delta(X, S)$ and $\delta(Y, S)$ is accepting and another is not accepting. Hence, a DFA is minimal if and only if all the states are distinguishable.

Algorithm 3

Step 1 – All the states Q are divided in two partitions – **final states** and **non-final states** and are denoted by P_0 . All the states in a partition are 0^{th} equivalent. Take a counter k and initialize it with 0.

Step 2 – Increment k by 1. For each partition in P_k , divide the states in P_k into two partitions if they are k -distinguishable. Two states within this partition X and Y are k -distinguishable if there is an input S such that $\delta(X, S)$ and $\delta(Y, S)$ are $(k-1)$ -distinguishable.

Step 3 – If $P_k \neq P_{k-1}$, repeat Step 2, otherwise go to Step 4.

Step 4 – Combine k^{th} equivalent sets and make them the new states of the reduced DFA.

Example

Let us consider the following DFA –

q	$\delta(q,0)$	$\delta(q,1)$
a	b	c
b	a	d
c	e	f
d	e	f
e	e	f
f	f	f

Let us apply the above algorithm to the above DFA –

- $P_0 = \{(c,d,e), (a,b,f)\}$
- $P_1 = \{(c,d,e), (a,b),(f)\}$
- $P_2 = \{(c,d,e), (a,b),(f)\}$

Hence, $P_1 = P_2$.

There are three states in the reduced DFA. The reduced DFA is as follows –

Q	$\delta(q,0)$	$\delta(q,1)$
(a, b)	(a, b)	(c,d,e)
(c,d,e)	(c,d,e)	(f)
(f)	(f)	(f)
